(57) **ABSTRACT**

Some embodiments disclosed herein relate to a lens component having one or more lenses attached to a retainer portion configured to removably attach to communication devices such as mobile phones, tablet computers, media players, and the like. The retainer portion may be configured so as not to interfere with a user's view of a display panel of the communication device. In some embodiments, a plurality of lenses may be provided, and the lenses may be removably attached to the retainer portion and may be interchangeable. A structure for providing a flash may also be provided. In some embodiments, additional features may be provided, such as attachment components to facilitate attachment to stability devices, such as tripods, and to user-wearable accessories.

LENSES FOR COMMUNICATION DEVICES

RELATED APPLICATIONS

This is a continuation of U.S. patent application Ser. No. 13/742,857, filed on Jan. 16, 2013, and entitled "Lenses for Communication Devices," now U.S. Pat. No. 8,891,187, which is a continuation of U.S. patent application Ser. No. 13/607,241, filed on Sep. 7, 2012, and entitled "Lenses for Communication Devices," now U.S. Pat. No. 8,593,745, which is a continuation of U.S. patent application Ser. No. 13/366,227, filed on Feb. 3, 2012, and entitled "Selectively Attachable and Removable Lenses for Communication Devices," now U.S. Pat. No. 8,279,544, which claims the benefit under 35 U.S.C. §119(e) of U.S. Provisional Patent Application No. 61/454,136, filed on Mar. 18, 2011 and entitled "Removable Lenses for Communication Devices," U.S. Provisional Patent Application No. 61/503,835, filed on Jul. 1, 2011 and entitled "Removable Lenses for Communication Devices," and U.S. Provisional Patent Application No. 61/585,857, filed on Jan. 12, 2012 and entitled "Selectively Attachable and Removable Lenses for Communication Devices," the entire contents of all of which are hereby incorporated by reference herein and made part of this specification for all that they disclose.

BACKGROUND OF THE INVENTIONS

1. Field of the Inventions

This invention relates generally to accessories for communication devices (e.g., mobile telephones, mobile texting devices, electronic pad devices, laptop computers, desktop computers, gaming devices, and/or devices capable of linking electronically to another device or to a network such as the Internet, etc.), and specifically to removable functional components for communication devices.

2. Description of the Related Art

In recent years, many advances in computer networking and processing technology have made it possible for communication devices to include cameras that permit users to capture images. In many cases, these images can be stored, processed, and transmitted. However, there are many design constraints on onboard cameras in communication devices that can limit the weight, size, expense, shape, adjustability, and overall quality of the lensing systems of such cameras. Consequently, many cameras in communications devices are inadequate for a wide variety of photographic needs and may produce poor quality photographic images. These deficiencies cannot be addressed by existing modular or detachable lensing systems for use with conventional film or digital cameras due to significant differences between such lensing systems and communication devices, including incompatibilities in attachment structures, weight, optics, size, transportation, storage, ergonomics, and/or portability.

BRIEF DESCRIPTION OF THE DRAWINGS

Certain embodiments of the inventions will now be discussed in detail with reference to the following figures. These figures are provided for illustrative purposes only, and the inventions are not limited to the subject matter illustrated in the figures.

FIGS. 1A-1I illustrate nine different views of an example of a removably attachable lens system for a communication device.

FIGS. 2A-2B illustrate the lens system of FIGS. 1A-1I being attached to examples of communication devices.

FIGS. 3A, 3B, 4A, 4B, 5A, 5B, 6A, and 6B illustrate other examples of lens systems being attached to other examples of communication devices.

FIGS. 7A-7I illustrate an example of a multiple lens system with a plurality of lenses used for different purposes.

FIGS. 8A-8I illustrate an example of a lens system with additional structures to facilitate attachment to a communication device.

FIGS. 9A-9E illustrate additional views of the lens system of FIGS. 8A-8I.

FIGS. 10A-10C illustrate the lens system of FIGS. 7A-7I being attached to an example of a communication device.

FIGS. 11A-11F illustrate examples of lens systems with lens portions that are adjustable with respect to retainer portions.

FIG. 12 illustrates an example of a lens retainer portion with an adjustment channel.

FIGS. 13A-13C illustrate an example of a communication device on which an example of a lens system from FIGS. 11A-11F has been attached.

FIGS. 14A-14B illustrate an example of a communication device with a light enhancement component on a lens system.

FIGS. 15A-15B illustrate an example of a communication device with another light enhancement component on a lens system.

FIGS. 16A-16F illustrate an example of a lens system that includes an adaptor.

FIGS. 17A-17B illustrate an example of a lens component that includes a mount feature.

FIGS. 18A-18C illustrate the lens component of FIGS. 17A-17B configured for mounting to a tripod.

FIGS. 19A-19C illustrate an example of a lens component that includes a storage or attachment feature along the side of the lens component for storing a lens or other device.

FIG. 20 illustrates examples of a lens system that includes an attachment to be used with an accessory such as a key-chain.

FIG. 21 illustrates examples of a lens system that includes an attachment to be used with an accessory such as a necklace.

FIG. 22 illustrates examples of a lens system that includes an attachment to be used with an accessory such as a bracelet.

FIGS. 23A-23E illustrate an example of a lens system that includes a lens hood.

FIGS. 24A-24D illustrate an example of a lens system that includes detachable lenses.

FIG. 25 illustrates an example of a lens system with an interior lens.

Many other types of communication devices besides those illustrated and described herein can be used.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT

The following detailed description is now directed to certain specific examples of embodiments of the disclosure. In this description, reference is made to the drawings wherein like parts are designated with like numerals throughout the description and the drawings. The inventions are not limited to the examples expressly illustrated or described in this specification.

Referring to FIGS. 1A-1I, an example of a removably attachable lens component 110 is illustrated in many different views. In some embodiments, as illustrated, the lens component 110 can generally comprise a retainer portion 112 and a lens portion 114. The retainer portion 112 is generally configured to be removably attachable to a communication device such that the lens portion 114 can be positioned in a

3

region generally covering or near an onboard camera lens in the communication device to enable the lens portion 114 to cooperate optically with the onboard camera, to provide optical enhancements, improvements, modifications, and/or alternatives. In some embodiments, as illustrated, the retainer portion 112 is shaped so as to attach to the communication device in a region and in a manner that permits a user to see all or virtually all of a viewing portion 131 of the communication device without obstruction or without appreciable obstruction.

For example, the retainer portion 112 can comprise a channel 116 with a plurality of sidewalls 118. The width of the channel 116, e.g., the distance between the respective sidewalls 118, can be configured to be generally complimentary to the thickness of a portion of the communication device(s) on which the retainer portion 112 is configured to attach. In some embodiments, the natural width of the channel 116 is approximately the same size or slightly smaller than the thickness of a corner, such as an upper corner, of the outside housing of a communication device near the light aperture of the onboard camera of the communication device.

In some embodiments, as illustrated, one or more of the plurality of walls 118 can have a curvilinear shape 119 along one or more edges to permit the retainer portion 112 to provide increased distance of contact along the edge of the communication device while diminishing the area across a transverse surface of the device that is obstructed by the retainer portion 112. For example, in some embodiments, as illustrated, the curvilinear shape along one or more edges of the walls 118 permits the retainer portion 112 to extend along and attach to at least a portion of two generally converging or generally perpendicular outer edges or sides of a communication device that is approximately as wide as the lens portion 114, while diminishing the amount of space on the front of the device that is blocked. In the example shown in FIGS. 1A-1I, the curvilinear shape of the edge of the walls 118 can avoid or omit a lower pointed or sharp corner that may otherwise extend into and obstruct the viewing portion of the communication device. In some embodiments, the retainer does not appreciably block or obstruct the viewing surface, as shown in FIG. 2B.

All or part of the retainer portion 112, such as one or more of the plurality of walls 118, can be made of a material (e.g., a polymer or a silicone) that is sufficiently flexible to permit deformation (e.g., compression, bending, or stretching) of one or more walls 118, so that the channel 116 can be temporarily widened while sliding the lens component 110 onto a communication device, but at least a portion of one or more of the walls 118 can be sufficiently stiff, rigid, or resilient to urge one or more of the plurality of walls 118 to return to its original position and thereby exert a gripping force against a portion of the communication device. The material of the retainer portion 112, especially the region on the inner side of the walls 118 within the channel 116, can also be tacky or somewhat slide resistant to enhance the gripping of the retainer portion 112 to the communication device. In some embodiments, the gripping force and/or slide resistance can reduce or eliminate the need to attach a permanent or temporary mounting component to the communication device. For example, the lens component 110 can be repeatedly attached to and removed from a communication device without requiring (though not prohibiting) installation on the communication device of a separate permanently or semi-permanently attached mounting component such as a bracket, magnet, adhesive, or other fastening component, thereby providing ease of installation while preserving the original overall shape, appearance, functionality, compatibility (e.g., with

4

other communication devices or cases), and/or feel of the communication device when the lens component is removed.

The retainer portion 112 can also comprise an upper wall 120 that can be shaped in some embodiments to generally correspond to the shape of one or more edges of a communication device. As illustrated, the upper wall 120 has a generally curvilinear shape with a rounded corner 122. The retainer portion 114 can also include one or more internal surface contours 124 configured to generally avoid interference with one or more external features on a communication device. For example, as illustrated, the channel 116 can include a surface contour 124 in the form of a groove to avoid interference or inadvertent contact with a button or other feature on a communication device when the lens component 110 is attached to the communication device. As illustrated, the sidewalls 118 of the retainer 112 can comprise one or more generally pointed or angular regions 129.

In some embodiments, as illustrated, the retainer portion 112 can be configured to grip two nonparallel sides of a communication device. For example, the retainer portion 112 can contact at least a first generally vertical side or edge surface 133 of a communication device and at least a second generally horizontal and generally orthogonal side or edge surface 134 of a communication device (e.g., the lateral side and the top side of the communication device) at the same time during use. In some embodiments, this contact by multiple generally perpendicular edges or surfaces permits repeatable adequately precise placement of the retainer portion 112 in a single attachment motion without requiring user adjustment of the location or structure of the retainer portion 112 during attachment. In some embodiments, two or more contacting surfaces in the retainer portion 112 can converge at an upper corner having a rounded external surface. In some embodiments, as illustrated, the retainer portion 112 is substantially smaller than the communication device to which it is configured to attach, or even substantially smaller than the viewing portion of the communication device to which it is configured to attach. In some embodiments, a retainer can be configured to contact only one side or edge (e.g., the generally vertical or the generally horizontal side or edge), such as by contacting both the front and rear surface of such side or edge but without also requiring contact with another side or edge. An example of such an embodiment can generally be formed from a retainer portion with a general U-shape comprising an upper wall, two side walls, and an opening on each side of the side walls.

In some embodiments, the retainer portion 112 can permit the lens component 110 to be attached to a communication device without requiring non-stock mounts on the communication device and without requiring dynamic mounts on the retainer portion 112 itself (e.g. fasteners, screws, adjustable clamps, etc.). Thus, a user can attach the lens component 110 to a corner of a communication device by simply sliding it, for example, onto the corner of the communication device, and can remove it by simply pulling it off, without requiring user adjustment during attachment. In some embodiments, as illustrated, the lens component 110 can remain on the communication device by way of a friction fit. The attachment to the communication device can avoid a residue deposit from adhesive, scratches to the exterior surface, or other damage or alteration of the communication device. In some embodiments, the retainer portion can be sufficiently wide and/or long so that it is adapted to receive an end and/or side region (e.g., two or more corners) of a communication device rather than merely one corner, and the other aspects of other embodiments disclosed herein can apply to such embodiments, including but not limited to the shape and materials of

5

construction and the accomplishment of a friction fit between the retainer portion and the end and/or side region of a communication device.

The lens portion 114 generally comprises a transparent lens 128, which is typically made of a glass or a polymer, and a securing structure 126. The securing structure 126 can be made of many different types of materials or combinations of materials, such as metals (e.g., aluminum or steel) or plastics. The securing structure 126 can include a generally wide-area opening for receiving the lens 128 and a generally narrow-area region for attachment to the retainer portion 112. In some embodiments, the securing structure 126 and the retainer portion 112 can be configured to slide or otherwise move with respect to each other in a limited manner to allow for adjustment of the position of the lens 128 with respect to the onboard camera lens of a communication device (e.g., for the purpose of addressing manufacturing tolerances in the location of the onboard camera lenses in some communication devices). As illustrated, the mechanism or structure for attachment or securement of the lens portion 114 to the retainer portion 112 can be separate from and/or can operate independently of the mechanism or structure for attachment or securement of the retainer portion 112 to the communication device. In some embodiments, as illustrated, the outside surface of the securing structure 126 can taper inwardly from the lens-receiving region to the retainer-attaching region to diminish the amount of material used in manufacturing and to diminish the size and weight of the retainer lens portion 114. In some embodiments, the lens component can be very small, such as less than or equal to about 2½ inches or less than or equal to about 1½ inches across.

The lens 128 can include multiple lenses or lens components. In some embodiments (not shown), the lens component 110 can comprise more complex lensing systems, such as lensing systems in which the focal length of the lensing system can be manually or electronically adjusted, such as with a lever or rolling dial or with electronic or motor control, which may be positioned between the lens 128 and the retainer portion 112. An electronic or motor control can be attached and adjusted using software in the communication device, either by a wired or wireless connection to the mobile communication device. Other specialized lenses in the lensing system can include a telephoto lens systems configured to enlarge images, wide-angle lenses, fish-eye lenses, macroscopic lenses, and microscopic lenses.

The lens 128 can also comprise coatings or other features to increase scratch resistance, diminish glare or reflection, or decrease or filter light transmitted through the lens 128. The lens component 110 can also include a cover configured to be fitted over the lens 128 during storage and transportation. The lens component 110 can comprise other storage and transportation features, such as a quick-release or other attachment structure to enable the lens component 110 to be conveniently carried by a user on a standard accessory carried by a person, such as a key ring, belt loop, bracelet, necklace, or other easily accessible location when not attached to a communication device. A collection or kit of different lens components 110 with various lenses having different lens features, including those described herein, can be provided within a storage case to address various photographic needs.

As illustrated in FIGS. 2A-2B and 3A-3B, the lens component 110 can be moved into proximity with a communication device 130, 134 that includes an onboard camera 132. In some embodiments, a lens component 110 can be sold or provided together as a system with the communication device 130, 134. The communication devices 130, 134 shown in FIGS. 2A-2B and 3A-3B are versions of the iPhone mobile

6

phone sold by Apple, Inc. The lens component 110 can be oriented so that the channel 116 is directed downwardly in general alignment with an edge or corner of the communication device 130 on which the lens component 110 will be mounted and rotated so that the lens 128 will be generally aligned with the onboard camera 132. As the channel 116 contacts the edge or corner of the communication device 130, the channel 116 may expand slightly as the walls 118 flex or bend outwardly. A restoring force produced by the retainer portion 112 can urge the walls 118 back toward their original position, which can help to retain the lens component 110 on the communication device 130 during use. The lens 128 can then temporarily provide an enlarged, better focused, clearer, or otherwise enhanced, altered, manipulable, or improved image for the onboard camera 132.

FIGS. 4A-4B and 5A-5B illustrate examples of lens components 200, 202 configured to be used on tablet-type communication devices 204, 206. In the illustrated examples, the communication device 204 is an iPad communication device sold by Apple, Inc., and the communication device 206 is a Galaxy tablet sold by Samsung. The lens components 200, 202 can include various features and structures of the lens component 110 illustrated and described in connection with FIGS. 1A-1I. In some embodiments, as illustrated in FIGS. 4A-B and 5A-5B, the lens components 204, 206 can include a retainer portion 208 with walls 210, 212 of different sizes and lengths. A longer or wider-area wall 212 can be provided on a side of the retainer portion 208 that is configured to suspend the lens 128 in front of the camera 132, while a shorter or smaller-area wall 210 can be provided on a side of the retainer portion 208 that is configured to extend over a portion of the surface on which the viewing portion of the communication device 204, 206 is located. The retainer portion 208 can be configured to securely attach the lens components 200, 202 while diminishing or eliminating obstruction of the viewing portion. An aperture or other functional access region 216 can be provided in the retainer portion 208 to permit access to controls or other interaction structures on the communication devices 204, 206 when the lens components 200, 202 are attached.

FIGS. 6A-6B illustrate an example of a lens component 302 with a retainer portion 308 that comprises a plurality of attachment arms 304 that include attachment structures, such as hook portions 306, that can partially or completely overhang on a portion of a communication device 306 or that are oriented in a generally transverse direction to the main portion of the attachment arms 304. As illustrated, the attachment arms 304 can be generally tapered from a central, wider portion to a peripheral, narrower portion to provide sufficient structural rigidity and retaining force. The lens component 302 can include the various features of the other lens components 110, 200 described herein. The communication device illustrated in FIGS. 6A-6B is an EVO communication device sold by HTC Corporation. The attachment arms 304 can assist in attaching the lens component 302 to a device, such as the EVO device, in which the camera 310 is not positioned near a corner of the device.

FIGS. 7A-7I illustrate several views of an example of a lens component 400 in which a plurality of lenses 402, 404 can be attached to the same retainer portion 406. In this example, the user can have at least two different options for the type of lens to use in a particular photographic application. For example, one of the lenses 402, 404 can provide a wide-angle view and another one of the lenses 402, 404 can provide a fish-eye view. Many other lens options are possible. For example, one or more lenses can be provided with different color filtering capabilities, different light attenuation capabilities, different

lens coatings (such as anti-reflection coatings), and differences in other optical properties to provide multiple user options. Different lenses can include any combinations of these or other optical features. The retainer portion **406** can include various features of the other retainer portions illustrated and described herein.

FIGS. **8A-8I** and **9A-9E** illustrate several views of an example of a lens component **400a** that is similar or identical in many ways to lens component **400** in FIGS. **7A-7I**. Lens component **400a** includes a channel **416** for receiving a portion of a communication device. The channel **416** includes an attachment-facilitating surface **418**. In the illustrated example, the attachment-facilitating surface **418** comprises an inwardly curved (e.g., sloped or slanted) surface positioned along the outer edge or slotted opening of the channel **416**. In some embodiments, the attachment-facilitating surface **418** can be positioned at or near an outer edge of the channel **416**. As illustrated, the attachment-facilitating surface can be thinner near the edge and can gradually become thicker as it progresses further into the channel **416**.

As the lens component **400a** is moved into an attachment position on a communication device, the attachment-facilitating surface **418** can provide an initial contact region or opening **420a** (see, e.g., FIGS. **8G** and **8H**) near the outer edge **422** that is effectively wider to facilitate proper orientation and attachment of the device by a user, and a narrower second region **420b** further within the channel **416** (or further from the edge of the lens component **400a**), thereby providing a more secure attachment surface as the lens component **400a** is moved further onto the attachment region of the communication device. In some embodiments, as illustrated, the width of the channel **416** can change between the initial contact region **420a** and the second region **420b** in a smooth, gradual, and/or curvilinear manner. Some embodiments can include many other types of shapes. For example, the attachment-facilitating surface **418** can include a discontinuous surface or a series of discrete ramps, protrusions, or grooves. An attachment-facilitating surface **418** can be included on any embodiment of a lens component and is not limited to use in the lens component **400a** as illustrated in FIGS. **8A-8I** and **9A-9E**.

As illustrated in FIGS. **10A-10C**, the user can select which of the plurality of lenses **402**, **404** to position in front of the camera **132** of the communication device **134** to achieve a desired photographic affect. In FIG. **10A**, the lens component **400** is moved into an attachment position on a communication device **134** such that a first (e.g., smaller-diameter) lens **402** is positioned in front of the onboard camera lens **132** and a (e.g., second larger-diameter) lens **404** is positioned on an opposite side of the communication device **134**. In this orientation, the smaller-diameter lens **402** is operative and the larger-diameter lens **404** is not operative. In FIG. **10B**, the lens component **400** is removed from the communication device, rotated about a vertical axis (e.g., approximately 180° in this example), and rotated about a horizontal axis to orient the channel **416** in general alignment with an attachment surface (e.g., a housing edge) of the communication device. In FIG. **10C**, the lens component **400** is again advanced onto the communication device **134** such that the larger-diameter lens **404** is positioned in front of the onboard camera lens **132** and the smaller-diameter lens **402** is positioned on an opposite side of the communication device **134**. In this orientation, the larger-diameter lens **404** is operative and the smaller-diameter lens **402** is not operative. In some embodiments, this configuration of a lens component **400** can conveniently permit multiple lens options without necessarily requiring the user to hold or store multiple discreet lens components. In

some embodiments, more than two lens types or features can be included in the lens component **400**, thereby providing the user with many lens options.

FIGS. **11A-11F** illustrate several views of an example of a lens component **500** in which a lens **502** is attached to a retainer portion **504**. The lens component **500** can be attached to a communication device **134** in a manner similar to the lens components described above. When the user has attached the lens component **500** to the communication device **134**, the user can adjust (e.g., tilt, swivel, or otherwise move) the lens **502** with respect to the communication device **134** (e.g., azimuthally, along the lens's vertical axis, along the lens's horizontal axis, a combination of these adjustments, etc.). The user can shift or otherwise move the lens **502** into a plurality of positions with respect to the retainer to diminish misalignment between the onboard lens in the communication device, or to change the viewing angle of the lens **502**, or for some other reasons. In some embodiments, the user can shift of otherwise move the lens **502** into at least a first and a second position, or at least a first, a second, and a third position, or gradually across an adjustment zone. In some embodiments, this adjustment can form a void **506** behind the lens portion **502**. The ability to adjust the lens **502** with respect to the communication device **134** can be advantageous in addressing manufacturing differences or tolerances in the location and/or alignment of the onboard camera lenses in some communication devices.

In some embodiments, the tilting of the lens **502** is facilitated by a pivot (not shown) on the portion of the lens facing the communication device **134**. The lens **502** is positioned in a channel formed by sidewalls **508** of the retainer portion **504**. In FIG. **11A**, the lens **502** is tilted to the left with respect to the communication device **134** such that a void **506** is formed between the rear of the lens **502** and a panel of the retainer portion **504** or the communication device **134** when attached, and the exterior walls of the lens portion **502** are non-parallel with the adjacent interior walls of the lens retainer portion **502**. As illustrated, the distance between the rear of the lens **502** and an interior edge, line, or cross-sectional region **507** of the retainer portion **504** is greater on a first side **509** than on a second side **511**. In this orientation, the lens **502** can compensate for an off-center alignment of the onboard camera of the communication device **134**. For example, in the adjusted orientation shown in FIG. **11A**, the central axis of the lens portion **502** can be brought into general alignment with the central axis of the onboard camera lens **132**. FIG. **11B** illustrates the lens **502** in a neutral position with respect to the communication device **134**. In this orientation, the lens **502** need not compensate for any off-center alignment of the onboard camera of the communication device **134**. FIG. **11C** illustrates the lens **502** tilted to the right with respect to the communication device **134**, forming a void **506** in a manner similar to FIG. **11A**. In this orientation, the lens **502** can compensate for a difference or off-center alignment or location of the onboard camera of the communication device **134**.

In some embodiments, the tilting of the lens **502** is facilitated by a ball and socket joint formed by a ball **510** on the portion of the lens **502** facing the communication device **134** and a socket **512** in the retainer portion **504**. This embodiment can generally function in a manner similar to the embodiment in FIGS. **11A-11C**. The ball portion **510** can approximate the shape of a generally oblate spheroid and can have one or more flat or straight portions. The ball portion **510** can be, but is not required to be, generally spheroid. In the embodiment illustrated in FIGS. **11D-11E**, the portion facing the communication device **134** is generally straight or flat. The ball **510** can be positioned within a socket **512** with a generally comple-

mentary shape, facilitating rotation of the lens 502 with respect to the retainer portion 502 and communication device 134. In FIG. 11D, the lens 502 is tilted to the left with respect to the communication device 134 such that a void 506 is formed between the ball 510 and socket 512 or the communication device 134. In this orientation, the lens 502 can compensate for mis correspondence in the alignment or location of the onboard camera of the communication device 134. FIG. 11E illustrates the lens 502 in a generally neutral position with respect to the communication device in which at least one wall of the retainer portion 504 can be generally parallel with either or both of the front or back surfaces of the lens portion 502. In this orientation, the lens 502 need not compensate for any mis correspondence in the alignment or location of the onboard camera of the communication device 134. FIG. 11F illustrates the lens 502 tilted to the right with respect to the communication device 134, forming a void 506 in a manner similar to FIG. 11D. In this orientation, the lens 502 can compensate for mis correspondence in the alignment or location of the onboard camera of the communication device 134 or otherwise help to adjust the nature of the photographic image produced. In the illustrated examples of FIGS. 11D-11F, at least one wall of the retainer portion 504 can be generally non-parallel with either or both of the front or back surfaces of the lens portion 102. As illustrated, the user can appropriately adjust the lens portion 502 with respect to the lens retainer portion 504.

As shown in FIG. 12, the lens retainer portion 504 can include one or more generally circular retaining walls 530 for receiving a lens portion 502 in an adjustable manner. The retaining walls 530 can include one or more apertures 535. A radially interior surface 537 of either or both of the apertures 535 can include a first adjustment structure, such as an adjustment channel 540 with a width and depth configured to receive a second adjustment structure on the lens portion 502, such as a ridge or bump. In the illustrated example, the adjustment channel 540 can be substantially smaller in width than the width of the interior surface 537 of the aperture 535 to provide a relatively small amount of restricted movement of the lens portion 502. For example, in some embodiments, the width of the adjustment channel 540 can be less than or equal to about 1.5 mm, and the interior of the adjustment channel 540 can be tapered or beveled toward a generally central portion or line to increase the force required to move the lens portion 502 away from a neutral position. The width of the ridge or bump on the lens portion 502 can be less than the width of the adjustment channel 540, such as less than or equal to about $\frac{3}{4}$ of the width of the adjustment channel 540. The first and second adjustment structures can fit closely or tightly together (e.g., in a radial interference fit) while permitting limited movement when a force is applied by a user in opposition to frictional forces between the adjustment structures. In this example, the lens portion 502 can be adjusted by a user to move with respect to the lens retainer portion 504 when moved in a deliberate manner, but the lens portion 502 and retaining portion 504 can generally remain in place until another adjustment. In some embodiments, the amount of adjustment can be relatively small, such as greater than or equal to about 0.5 degrees and/or less than or equal to about 2.5 degrees between the orientation of the central longitudinal axis of the lens portion 502 in the original position as compared to the orientation of the central longitudinal axis of the lens portion 102 in the fully adjusted position. In some embodiments, the lens portion 502 can be adjusted to various positions between (or outside of) these points or ranges. The amount of movement between the rear surface of the lens portion 502 and the lens retainer portion 504 can be relatively

small as well, such as greater than or equal to about 0.1 mm and/or less than or equal to about 1.0 mm between the original orientation and the fully adjusted orientation.

As illustrated in FIGS. 13A-13C, the user can adjust the tilt of the lens 502 with respect to the communication device 134 to improve the alignment or other correspondence between the lens 502 and the onboard camera of the communication device 134. In FIG. 13A, the lens 502 is in a neutral position with respect to the communication device 134. The image on the screen 560 of the communication device 134 is off-center to the left, as evidenced by the leftward orientation of the vignetting which would normally be centered about the image. FIG. 13B shows the user 590 tilting the lens 502 to the right to compensate for the off-center image on the communication device 134. FIG. 13C illustrates the corrected image, with the vignetting centered about the image even though the onboard camera of the communication device is not aligned properly. In some embodiments, the tilt of the lens 502 can be adjusted while the user 590 is viewing a live image from the onboard camera on the screen 560 of the communication device 134, providing real-time feedback to the user about whether the correct adjustment is being made.

FIGS. 14A-14B illustrate two views of a lens component 600 with a lens portion 630 and a light-enhancing feature, such as a light pipe 610. The light pipe 610 can be mounted to the retainer portion 660 or to some other portion of the lens component 600. The light pipe 610 conveys light from a light source, such as a flash, to an exit point 620 so that it may illuminate the area to be photographed. In some embodiments, the light pipe 610 is made from material which facilitates conveyance of light from the flash to the area to be photographed. In some embodiments, the interior of the light pipe 610 is lined with material which facilitates conveyance of light from the onboard flash to the area to be photographed. The position of the flash 650 on the communication device 134 illustrated in FIGS. 14A-14B is close enough to the onboard camera 132 that the lens component 600 generally covers or otherwise obstructs the flash 650 when it is attached to the communication device 134. In some circumstances, this may prevent light from the flash 650 from enhancing photographs taken when the lens component 600 is attached. The light pipe 610 conveys the light from the flash 650 to the exit point 620, and from there the light travels normally to illuminate the area in front of the camera.

In some embodiments, the light pipe 610, retainer portion 660, and/or some other portion of the lens component 600 can be configured to generally or entirely surround the flash 650 and/or other region from which light emanates to inhibit or prevent undesirable light transfer or leakage outside of the pathway from the onboard flash into the light pipe 610. Such an undesirable transfer or leakage may include light from the onboard flash moving into the rear side of the lens portion 630 of the lens component 600 or light from the onboard flash moving outside of the region between the retainer portion 660 of the lens component 600 and the communication device.

In some embodiments, the retainer portion 660 or another component can be formed from various materials, including polymers (e.g., polycarbonate), metals (e.g., aluminum), etc., or some combination thereof. For example, at least a portion of the retainer portion 660 can be formed using a multi-step molding process, such as multi-shot injection molding, inserting molding, or overmolding, and/or the retainer portion 660 can include a coating, such as an adhesive, paint, or deposited film, to provide a region on the interior and/or exterior of the retainer portion 660 that has a different durometer or appearance than another portion of the retainer portion 660. In some embodiments, a harder shell or exterior can be

11

provided in conjunction with a softer interior surface. For example, an interior region of the retainer portion **660** that is intended to be positioned in contact with the corner of the communication device can comprise a surface that is softer and/or more tacky than an exterior region or a supporting region of the retainer portion **660**. In some embodiments, the softer or more tacky surface can provide an enhanced light seal by compressing against the communication device to inhibit or prevent light leakage.

FIGS. **15A-15B** illustrate two views of a lens component **600a** with a light pipe **610a**. In many respects, the light pipe **610a** is similar or identical to the light pipe **610** described above. The exit point **620a** of the light pipe **610a** can generally or completely surround the lens **630a**, providing a generally ring-shaped flash. This can be particularly desirable for use in macro (or close-up) photography. The light-enhancing feature can also be provided by a flash or other light source on the lens component **600**, without requiring use or connection with an onboard flash.

In some embodiments, a light-enhancement feature can include an externally attachable flash component connected to the lens component **110** that can be selectively configured to be in electronic communication with the communication device (e.g., by way of a wireless protocol such as the Bluetooth® protocol, or by way of a wired connection such as a USB or serial connection, etc.). The flash can be powered by and/or actuated by the communication device. In some embodiments, the flash can pivot, tilt, or otherwise move with respect to the retainer portion **112** to direct light as desired by the user.

In some embodiments, as illustrated and described herein, lens components can include retainer portions with attachment structures configured to be removably attached to communication devices, even when the communication devices themselves are generally smooth or flat and do not have corresponding attachment structures in the region near the onboard camera. In this way, the communication devices are not required to be permanently or temporarily modified, reconfigured, defaced, or otherwise altered in appearance to permit attachment of the lens components. In some embodiments, this arrangement can permit uninterrupted and unobstructed, normal use of the communication device when the lens component is removed. However, in some embodiments, modifications to the communication devices may be useful or necessary to attach the lens components.

FIGS. **16A-16F** illustrate views of a lens system **700**. The lens system **700** can include a lens component **702**. The lens component **702** can be similar to other lens components described herein. For example, the lens component **702** can comprise similar or identical structures as lens component **400** or **400a**. The lens component **702** can include one or more lenses **704**, **706** that are attached to (e.g. releasably coupled to, or integrally formed with) the same retainer portion **708**. With more than one lens, the user can have at least two different options for the type of lens to use in a particular photographic application. For example, one of the lenses **704**, **706** can provide a wide-angle view and another one of the lenses **704**, **706** can provide a fish-eye view. The retainer portion **708** can include various features of the other retainer portions illustrated and described herein. For example, the retainer portion **708** can include a channel **709**.

The lens system **700** can further include an adaptor **710**. The adaptor **710** can comprise a separate or independent piece from that of the lens component **702**.

The adaptor **710** can include a first adaptor connection portion **712**. The first adaptor connection portion **712** can be configured to be removably attachable to a communication

12

device **720** that has a shape that is different from the standard communication device to which the lens component **702** is normally configured to attach, for example as shown in FIG. **16D**. The first adaptor connection portion **712** can include a channel **714**. The channel **714** can be sized and/or shaped to correspond to the size and/or shape of at least a portion of the communication device **720**, such that the adaptor **710** can slide over a portion (e.g. a corner) of the communication device **720**, and be held in place on the communication device **720** (e.g., by way of a friction fit).

The adaptor **710** can further include a second adaptor connection portion **716**. The second adaptor connection portion **716** can be sized and/or shaped such that it is received within the channel **709** on the lens component **702**. The second adaptor connection portion **716** can include at least one opening **718** to permit optical communication between the lens **704**, **706** and a corresponding onboard camera **722** on the communication device **720**.

The adaptor **710** and lens component **702** can be positioned such that the lens **704**, **706** is positioned in a region generally covering or near the onboard camera **722** in the communication device **720** to enable the lens **704**, **706** to cooperate optically with the onboard camera, to provide optical enhancements, improvements, modifications, and/or alternatives. In some embodiments, as illustrated, the adaptor **710** and lens component **702** are shaped so as to attach to the communication device **720** in a region and in a manner that permits a user to see a viewing portion of the communication device **720** without obstruction or without appreciate obstruction.

The lens component **702** can be removably attached to the adaptor **710** in a variety of manners. For example, the lens component **702** can be attached solely via a friction fit between the retainer portion **708** and the second adaptor connection portion **716**. In some embodiments, the lens component **702** can snap into place on top of the adaptor **710**. Other attachment options are also possible.

The adaptor **710** can allow the lens component **702** to be used with one or more different communication devices. For example, the adaptor **710** can allow the lens component **702** to be used with a communication device that is different in size, thickness, and/or shape than one that the lens component **702** is typically designed for. For example, in some embodiments, the communication device **720** can comprise an iPod Touch device, manufactured by Apple, Inc., and another communication device **134** can comprise an iPhone, also manufactured by Apple, Inc. The iPhone is typically larger, and thicker, than the iPod Touch. If the lens component **702** is designed and sized to specifically fit onto the iPhone, but not onto the iPod Touch, the user can conveniently and simply use the adaptor **710** in order to use the lens component **702** with the communication device **720**.

FIGS. **17A-17B** illustrate an example of an attachment component **800** for use in applications where a communication device is intended to be mounted temporarily on a support structure to take a photo or video. The attachment component **800** can include one or more lenses **802**, **804** that are attached to the same retainer portion **806**. The retainer portion **806** can include a channel **808**, similar or identical to the channels described above, for attaching the attachment component **800** to a portion (e.g. corner) of the communication device **134**. In some embodiments, the retainer portion **806** can further include stabilizing or securing members such as at least one or more elongate ridges **810**, **812**. The elongate ridges **810**, **812** can extend away from the lens **802**, **804**, and can be used to grasp onto and/or hold the attachment component **800** in place on the communication device **134**. In some

13

embodiments, as illustrated, the width of the elongate ridges **810**, **812** is less than the thickness of the communication device to which the lens component is configured to attach and the elongate ridges **810**, **812** extend across the front viewing surface of the communication device along a narrow front edge and terminate before obscuring any appreciable portion of the viewing area. The retainer portion **806** can also include a connector opening **814** at one end of the attachment component **800**.

As illustrated in FIG. 17B, the attachment component **800** can be attached to the communication device **134** (e.g. iPhone), such that the elongate ridges **810**, **812** extend over and grasp onto a side edge **816** of the communication device **134**. The ridges **810**, **812** can help to hold the attachment component **800** in place on the communication device **134**. Other types of structure, other than ridges **810**, **812** can also be used.

As illustrated in FIGS. 18A-18C, the attachment component **800** can be attached to a support structure **818** (e.g. a tripod). For example, attachment component **800** can be attached to a base portion **820** of the support structure **818**. The base portion **820** can be screwed into, or otherwise attached to, the retainer portion **806** of the attachment component **800**. In some embodiments the connector opening **814** can include internal threading, and the base portion can include a screw or other structure that has external threads, such that the base portion **820** can be screwed into the connector opening **814**. Other types of connection are also possible, including a snap-fit or other type of connection mechanism that permits a quick, releasable connection between the attachment component **800** and the support structure **818**.

In some embodiments, the base portion **820** of the support structure **818** can either include, or be connected with, a mounting arm **822**. In some embodiments the retainer portion **806** of the attachment component **800** can comprise the mounting arm **822**. The mounting arm **822** can be used to adjust the position of the communication device **134**. For example, as illustrated in FIG. 18C, without the mounting arm **822**, the communication device **134** is in a generally horizontal or landscape position on top of the support structure **818**, whereas with the mounting arm **822**, as illustrated in FIG. 18B, the communication device **134** is positioned to a side of the base portion **820**, and is in a vertical position. Other types of mounting arms or structures are also possible. In some embodiments, as illustrated, the attachment component **800** comprises one or more lenses, and in some embodiments, the attachment component **800** has no lenses.

FIGS. 19A-19C illustrate a lens component **900** that permits storage of additional lenses, lens caps, or other devices. The lens component **900** can include one or more lenses **902**, **904** that are attached to the same retainer portion **906**. The retainer portion **906** can include a channel (not shown), similar to the channels described above, for attaching the lens component **900** to a portion (e.g. corner) of the communication device **134**.

The lens component **900** can further include at least one attachment feature **908**. The storage attachment feature **908** can comprise an opening, ridge, button, or other structure located generally orthogonally along the lens component **900** that is configured to contact, hold, and/or receive a device. For example, the attachment feature **908** can comprise an opening configured to receive a portion of lens **902**. The storage attachment feature **908** can be located on the retainer portion **906**. The storage attachment feature **908** can attach (e.g. releasably attach) to a plurality of different sized lenses, including but not limited to lenses **902** and/or **904** as illus-

14

trated. The storage attachment feature **908** can also, or alternatively, releasably attach to a lens cap (not shown), or other types of devices.

In some embodiments, the storage attachment feature **908** can permit one or more devices (e.g. lenses) to be stored and/or carried along a side of the lens component **900** until needed for use. When a device is needed for use, the device can be removed from the storage attachment feature **908**, and attached along a different area of the lens component **900**. For example, in some embodiments, and as illustrated in FIG. 19A, the lens **902** can be removed from an opening **910** along the retainer portion **906**. The opening **910** can include threads or other structure generally for holding the lens **902**. Once removed, the lens **902** can be attached to the storage attachment feature **908** along the side of the lens component **900**, as illustrated in FIG. 19B. At such time, a different lens can then be inserted into the opening **910** if desired. Once the lens **902** is needed again, the lens **902** can be removed from the storage attachment feature **908**, and again placed back into the opening **910**.

FIGS. 20-22 illustrate examples of a lens system **1000** that are used with person-carried accessories such as keys, necklaces, bracelets, or other devices. The lens system **1000** can include a lens component **1002**. The lens component **1002** can be similar or identical to any of the lens components described herein. For example, the lens component **1002** can be similar to lens component **400** or **400a**. The lens component **1002** can include one or more lenses **1004**, **1006** that are attached to the same retainer portion **1008**. The retainer portion **1008** can include various features of the other retainer portions illustrated and described herein. For example, the retainer portion **1008** can include a channel **1010**.

The lens system **1000** can include an attachment component such as a plug **1012**. The attachment component can be configured to remain on or connected with a person-carrier accessory, while the lens component **1002** can be selectively detached during use. The plug **1012** can be sized and shaped so as to be received by the channel **1010**. The plug **1012** can include one or more accessory attachment features **1014**. The accessory attachment feature **1014** can comprise, for example, a small ring or half-ring that protrudes from the rest of the plug **1012**. The accessory attachment feature **1014** can be attached to a set of keys **1016**, necklace **1018**, bracelet **1020**, or any other similar device.

The lens system **1000** can allow a user to wear and/or carry the lens component **1002** with him or her, in an easy and convenient manner. The lens component **1002** can be quickly removed from the plug **1012** and used with a communication device, such as one of the communication devices described herein, and then returned again to the plug **1012** and/or keys **1016**, as illustrated in FIG. 20, necklace **1018** as illustrated in FIG. 21, bracelet **1020** as illustrated in FIG. 22, etc. once the user is done.

FIGS. 23A-23E illustrate an example of a lens system **1100** that can be used to reduce lens flare and protect a lens. The lens system **1100** can include a lens component **1102**. The lens component **1102** can include structures that are similar or identical to the lens components described herein. For example, the lens component **1102** can be similar to lens component **110**. The lens component **1102** can include one or more lenses **1104** that are attached to the same retainer portion **1106**. The retainer portion **1106** can include various features of the other retainer portions illustrated and described herein. For example, the retainer portion **1106** can include a channel (not shown).

The lens system **1100** can further include a lens hood **1108**. The lens hood **1108** can be a separate piece that is configured

15

to attach to the lens component **1102**. The lens hood **1108** can comprise an opening **1110** configured to fit over the lens **1104**. The lens hood **1108** can comprise flared portions **1112**, **1114** that extend away from the opening **1110**. The flared portions **1112**, **1114** can be configured to provide protection for the lens **1104**, so as to reduce lens flare.

In use, the lens hood **1108** can be releasably attached to the lens **1104**, for example by simply sliding the opening **1110** of the lens hood **1108** over an edge **1116** of the lens **1104**. The lens hood **1108** can be held in place via friction fit, though other connection mechanisms are also possible. Once attached, the flared portions **1112**, **1114** can be positioned as desired by twisting or rotating the lens hood **1108**. The flared portions **1112**, **1114** can then protect the lens **1104** while the lens **1104** is in use. Once the lens **1104** is no longer in use, the lens hood **1108** can be removed from the lens component **1102**, turned around **180** degrees, as illustrated in FIGS. **23C**-**23E**, and placed back over the lens **1104**. In this position, the lens hood **1108** can not only be easily stored for future use, but can also help to protect the lens **1104** and/or lens component **1102** from damage and/or wear.

FIGS. **24A-24D** illustrate an example of a lens system **1200** that can include a selectively attachable and detachable lens or a plurality of different selectively attachable and detachable swappable lenses. The lens system **1200** can include a lens component **1202**. The lens component **1202** can be similar to one of the lens components described herein. For example, the lens component **1202** can be similar to lens component **110**. The lens component **1202** can include one or more lenses **1204** that are attached to the same retainer portion **1206**. The retainer portion **1206** can include various features of the other retainer portions illustrated and described herein. For example, the retainer portion **1206** can include a channel (not shown).

As described above, the lens system **1200** can include the ability to swap lenses. Thus, the lens component **1204** can be removably attached to the retainer portion **1206**. For example, the retainer portion **1206** can include a lens attachment portion **1208**. The lens **1204** can be removably attached to the retainer portion **1206** at the lens attachment portion **1208**. For example, the lens attachment portion **1208** can comprise an opening with threads, and the lens **1204** (or other lens) can be screwed into the opening **1208**, or the lens can snap-fit or otherwise simply be pushed into the opening **1208**. Other connection mechanisms are also possible. For example, the lens can be temporarily locked in with a bayonet mount, or a magnetic mount or other structure can be used.

The lens system **1200** can further include one or more additional lens components, such as a second lens component **1210**. In some embodiments, the second lens component **1210** can comprise a lens **1212** with a lens hood **1214**. The second lens component **1210** can be a separate piece that is configured to attach to the retainer portion **1206**, similar to lens **1204**. For example, the second lens component **1210** can be attached to the lens attachment portion **1208**. Thus, depending on user preference, a user can select a lens **1204**, a lens **1212** with hood **1214**, or other types of lenses for use with the lens system **1200**.

FIG. **25** illustrates an example of the lens system **1200** that includes one or more interior lens components. In some embodiments, the lens system **1200** can include an embedded lens component **1216**. The retainer portion **1206** or the embedded lens component **1216** can comprise a connection portion, such as a threaded portion, that can be similar to the lens attachment portion **1208**, described above. The threaded portion can facilitate removably attaching lenses, such as lens **1204**, to the retainer portion **1206**. In some embodiments, the

16

retainer portion **1206** and/or the embedded lens component **1216** can include a lens **1218**. As illustrated, the embedded lens component **1216** can be generally flush with or inset within the walls of the retainer portion **1206**. In some embodiments, the lens **1218** can be a macro lens configured to magnify an image by at least about **4×** magnification. Many different magnifications are possible. In some embodiments, the lens **1218** can be a macro lens configured to apply a magnification of at least about **5×** magnification and/ or less than or equal to about **15×** magnification, etc. In some embodiments, multiple lenses can be configured to provide a variable optical magnification (e.g., a zoom feature) by permitting manipulation of the distance between the lenses, such as with a lever or rotating actuator (e.g., a thumb wheel).

Although this invention has been disclosed in the context of a certain preferred embodiments and examples, it will be understood by those skilled in the art that the present invention extends beyond the specifically disclosed embodiments to other alternative embodiments and/or uses of the invention and obvious modifications and equivalents thereof. It is also contemplated that various combinations or subcombinations of the specific features and aspects of the embodiments may be made and still fall within the scope of the invention. Accordingly, it should be understood that various features and aspects of the disclosed embodiments can be combine with or substituted for one another in order to form varying modes of the disclosed invention.

The following is claimed:

1. A removable lens device for modifying an image of light received by an onboard camera of a mobile communication device, the removable lens device comprising:

- a retainer portion with a first side and a second side, the retainer portion being configured to be removably attachable to a mobile communication device;
- a first lens attached or attachable to the first side of the retainer portion; and
- a second lens attached or attachable to the second side of the retainer portion;

the retainer portion being configured to position one of either the first lens or the second lens, when the lens is attached to the retainer portion, in a location generally in front of a corner region of a front face of the mobile communication device, so as to be generally aligned with an onboard camera of the mobile communication device, when the retainer portion is removably attached to the mobile communication device, and the retainer portion being configured to simultaneously position the other of either the first lens or the second lens, when the lens is attached to the retainer portion, in a location generally behind a rear face of the mobile communication device;

wherein the first and second lenses are not configured to be in optical communication with each other when the retainer portion is attached to the mobile communication device; and

wherein the locations of the first lens and the second lens with respect to the mobile communication device are configured to be generally switchable by detaching and separating the retainer portion from the mobile communication device, rotating the retainer portion about a generally vertical axis, and reattaching the retainer portion to the mobile communication device.

2. A combination of the removable lens device of claim **1** and the mobile communication device.

3. The removable lens device of claim **1**, wherein the retainer portion is configured such that, when attached to the mobile communication device, the first and second lenses are

17

both generally positioned along a single axis that is generally perpendicular to both the front and rear faces of the mobile communication device.

4. The removable lens device of claim 1, further comprising a groove on an underside configured to receive an edge of the mobile communication device.

5. The removable lens device of claim 4, wherein the groove is configured to extend less than the entire distance across a top edge of a mobile communication device when the lens device is attached to the mobile communication device.

6. The removable lens device of claim 1, wherein the first and second lenses are both configured to be near the same vertical edge of the mobile communication device when the lens device is attached to the mobile communication device.

7. An auxiliary lens device for modifying an image received by an onboard camera of a communication device, the auxiliary lens device comprising:

a retainer portion with a first side and a second side, the retainer portion being configured to be removably attachable to a communication device;

a first lens attached or attachable to the first side of the retainer portion; and

a second lens attached or attachable to the second side of the retainer portion;

the retainer portion being configured to position one of either the first lens or the second lens, when the lens is attached to the retainer portion, in a location in front of a front face of the communication device, so as to generally cover a front onboard camera lens of the communication device, when the retainer portion is removably attached to the communication device, and the retainer portion being configured to simultaneously position the other of either the first lens or the second lens, when the lens is attached to the retainer portion, in a location generally behind a rear face of the communication device

wherein the location of the first lens, when attached to the retainer portion, is switchable to the location of the second lens by removing the retainer portion from the communication device and reattaching the retainer portion in an opposite-facing orientation; and

wherein the lens in front of the front face of the communication device is in optical communication with the front onboard camera, when the retainer portion is removably attached to the communication device, and the lens behind the rear face of the communication device is not in optical communication with the front onboard camera, when the retainer portion is removably attached to the communication device.

8. The auxiliary lens device of claim 7, wherein the orientation of the auxiliary lens device is configured to be changed to generally switch the locations of the first and second lenses when attached to the communication device.

9. The auxiliary lens device of claim 8, wherein the removable lens device is also configured to be rotated about an axis that is generally perpendicular to an axis extending through a front face of either of the first and second lenses to generally switch the locations of the first and second lenses when attached to the communication device.

10. A combination of the auxiliary lens device of claim 7 and the communication device.

11. The auxiliary lens device of claim 7, wherein the retainer portion is configured such that, when attached to the communication device, the first and second lenses are both generally positioned along a single axis that is generally perpendicular to both the front and rear faces of the communication device.

18

12. The auxiliary lens device of claim 7, further comprising a groove on an underside configured to receive an edge of the communication device.

13. The auxiliary lens device of claim 12, wherein the groove is configured to extend partially across a top edge of a communication device when the auxiliary lens device is positioned on the communication device.

14. The lens device of claim 7, wherein the first and second lenses are both configured to be near the same vertical edge of the communication device and farther away from an opposing vertical edge of the communication device when the auxiliary lens device is positioned on the communication device.

15. A method of providing an auxiliary lens assembly for a communication device, the method comprising:

providing a first lens;

providing a second lens;

providing a retainer portion configured to receive the first and second lenses in respective different locations on the retainer portion so as to permit a user to contact an edge of a communication device with the retainer portion to position one of the lenses near an onboard camera on a first surface of the communication device while positioning the other of the lenses near a second surface of the communication device, such that the second lens is not in optical communication with the first lens, wherein the second surface of the communication device is generally opposite from the first surface of the communication device, and wherein the orientation of the first and second lenses are configured to be fixed with respect to the communication device while the lenses are attached to the retainer portion and while the retainer portion is attached to the communication device.

16. The method of claim 15, wherein the first and second lenses are not in optical communication with each other when attached to the communication device.

17. The method of claim 16, wherein the first surface is the front surface of the communication device and the second surface is the rear surface of the communication device.

18. The method of claim 17, wherein the retainer portion is configured to receive an edge of the communication device in a groove of the retainer portion to removably secure the retainer portion to the communication device.

19. The method of claim 18, wherein the first and second lenses are configured to produce different optical effects.

20. The method of claim 19, wherein the retainer portion is configured to attach on only one corner of the communication device.

21. The method of claim 20, wherein the retainer portion is configured to attach by a friction fit between the retainer portion and the corner of the communication device.

22. A method of attaching an auxiliary device to a mobile communication device, comprising the steps of:

obtaining an auxiliary device comprising a retainer portion with at least a front wall and a light-transmitting portion, a first optical portion configured to receive light on a first side of the auxiliary device, and a second optical portion configured to receive light on a second side of the auxiliary device, the first and second sides being generally opposite from each other;

attaching and securing the retainer portion to the mobile communication device in a single motion near an onboard camera of the mobile communication device such that the retainer portion contacts at least two generally perpendicular sides of the mobile communication device in a corner region of the mobile communication device;

wherein the retainer portion is not required to contact additional sides of the mobile communication device in order to remain attached to the mobile communication device and wherein the orientation of the retainer portion does not change when the retainer portion is attached to the mobile communication device. 5
